

Move semantics optimization

```
class DataProcessor {  
private:  
    std::vector<std::string> data;  
  
public:  
    // Before: Copy semantics  
    void setData(const std::vector<std::string>& input) {  
        data = input; // Expensive copy  
    }  
  
    // After: Move semantics (automatically suggested by agent)  
    void setData(std::vector<std::string>&& input) {  
        data = std::move(input); // Efficient move  
    }  
};
```
