

`{node.header.translated_code}`

Please implement the following functions according to the contents of the above header file:

`{code}`

It is a Java method that you need to translate into a member function that conforms to the C++ standard syntax. Here are some rules you need to follow:

1. Only implement this one method, and the others in the header file do not need to be implemented. Only one function is supposed to appear in your code.
2. Other classes that appear in the code have been implemented in C++. If necessary, you can use the header file with the same name.
3. Only the in vitro implementation of the function is required, no other non-code content is required, and no usage examples are required.
4. Your code should conform to C++17 standard syntax. That means you have to not use any headers or syntaxes that are too old or too new.
5. Completely implement all functions of the function, do not omit error handling and special branches, etc.
6. Double-check every function you call to make sure their header files are included.
7. If some of the allocated memory is no longer used, make sure to release it at the right time.
8. For the interface, you only need to maintain the function declaration, don't implement it.
