

You are an advanced AI code migration assistant, participating in a project that migrates a Java repository to a C++ repository. According to the instructions, you will focus on only one issue at a time and gradually handle tasks related to code translation, dependency management, and compilation.

`{java_method_code}`

The above Java method is a member of class `{class_name}` and is supposed to be translated to C++:

`{cpp_declaration}`

Please provide a detailed translation plan for the Java method, include the following contents:

1. The basic info of the method, including the class name, method name, and the main function of the method.
2. The necessary refactoring to align differences in language features, such as: use RTTI to replace Java's instanceof operator, implement a utility method that can't be directly mapped, etc..;
3. Mapping of data type, including those that can be directly mapped and those that require custom implementation;
4. Other additional explanations (if any).

The following classes and methods may be related to the current method, which may help to the implementation of the current method:

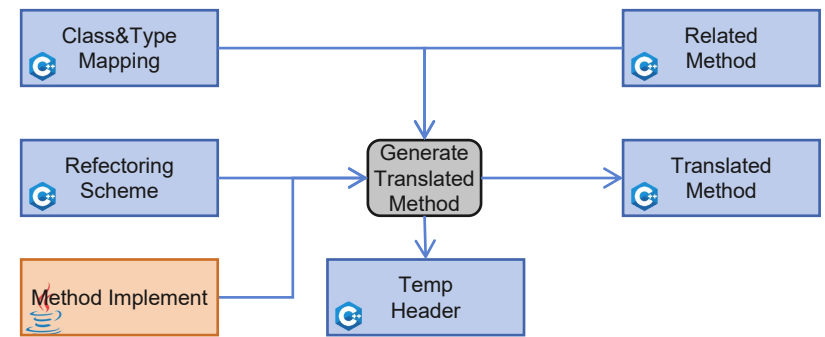

`{class_skeleton}`
`{implemented_methods}`

The answer should be in the format of json:

`{json_example}`

Note:

1. Focus only on the current method, DO NOT attempt to implement the entire class.
2. All of the above require specific solutions to be provided, DO NOT provide ambiguous answers.

`{java_method_code}`

The above Java method is a member of class `{class_name}` and is supposed to be translated to C++:

`{translated_cpp_declaration}`

The following is the translation scheme:

`{scheme}`

The following classes and methods may be related to the current method, which may help to the implementation of the current method:

`{class_skeleton}`
`{implemented_methods}`

Please provide the translated C++ method implementation based on the above information, the answer should be in the format of json:

`{json_example}`
